Abstract: Robotic-assisted surgery is now well established and has been introduced into the field of thoracic surgery. We are going to share the experience of robotic surgery for right inferior lobectomy. A 61-year-old patient underwent robotic-assisted thoracic surgery for a primary lung adenocarcinoma. The patient was discharged on postoperative day 6 without any perioperative complications. The pathological stage was T1aN0M0 (stage IA). Our result showed the robotic-assisted thoracoscopic surgery was a safe and feasible surgical approach for non-small cell lung cancer (NSCLC).

Clinical data

A 61-year old woman with chronic obstructive pulmonary disease but no history of smoking was found to have a right inferior lobe mass by computed tomography (CT) scan during health checkup. Adenocarcinoma was diagnosed by lung puncture. The right main and upper lobe bronchus were not involved. Positron emission tomography (PET)-CT and cerebral magnetic resonance imaging showed no distant metastasis. Preoperative blood analysis and tests of lung, cardiac, liver and renal function were normal. No superficial lymph node enlargement was detected on physical examination. The clinical stage was cT1N0M0 (stage IA). Informed consent for robotic-assisted thoracic lobectomy was obtained from patient before operation (Figure 1).

Procedure

Anesthesia and body position

The patient received general anesthesia by double-lumen endotracheal intubation and was placed in the lateral decubitus position and in a jackknife position (Figure 2).

The port positions

After the patient was prepped and draped in the usual manner, we placed five ports as follows: a 12-mm camera port was placed in the 8th intercostal space (ICS) at the mid axillary line, and three 10-mm working ports were placed separately in the 5th ICS at anterior axillary line (#1 arm), 8th ICS at the right posterior axillary line (#2 arm), and the right 8th ICS which was 2 cm from the spine (#3 arm). Finally, an auxiliary port was created in the 7th ICS between the camera port and the right working port, about 8-cm far from the right working port (Figure 3).
The robot patient cart was positioned directly above the operating table. Two bipolar forceps and one unipolar cautery hook were attached to the arms. An incision protector was placed in the auxiliary port.

discharged 6 days later after surgery. No complications were occurred during hospitalization. The pathological stage was T1aN0M0 (stage IA).

**Comment**

Currently in our institution, the 3- or 4-arm method is mainly used. When the patient has a small physique, the 3-arm method may reduce interference between arms. However, the 4-arm method become more popular, because the visual field can be set at any angle in the thoracic cavity. Therefore, the position of each port is important. Nakamura *et al.* suggested a 9-cm distance should be set between ports to reduce interference between surgical arms (1). In our experience, a distance of 8–10 cm effectively reduces the interference between arms. Cerfolio *et al.* described a complete robotic lobectomy setting all the ports concentrating in the 7th ICS (2,3), and this method was considered applicable for all lobectomies (1).
