Abstract: Robotic-assisted surgery is now widely used in the field of thoracic surgery. We are going to share the experience of robotic surgery for left upper lobectomy. A 63-year-old patient underwent robotic-assisted thoracic surgery for a primary non-small cell lung cancer. The patient was discharged on postoperative day 3 without any perioperative complications. The pathological stage was T1aN0M0 (stage IA).

Keywords: Robotic-assisted thoracoscopic surgery; left upper lobectomy

Clinical data

The patient was a 63-year-old man admitted because of cough and pulmonary nodule detected by computed tomography (CT). Chest CT (Figure 1) showed a mass located in the posterior segment of the left upper lobe (2.5 cm × 2 cm) that was lobulated with burr-like edges. The mass did not change after anti-inflammation therapy. The positron emission tomography-CT SUV max was 6.5 and malignancy was considered. The mediastinal lymph node was negative and there was no distant metastasis. The patient’s complaints did not include chills, low fever, night sweats, hoarseness, or fatigue of upper limbs. The cardiopulmonary function, blood gas analysis, and laboratory tests were normal. There was no positive sign or supraclavicular lymph node enlargement on physical examination. He had no past medical history. Preoperative stage was cT1N0M0 (IA). Informed consent for robotic-assisted thoracic lobectomy was obtained from patient before operation.

Operation steps

Anesthesia and body position

After the induction of general anesthesia, the patient was placed in a right lateral decubitus position under double-lumen endotracheal intubation. With his hands placed in front of his head, the patient was fixed in a jackknife position with single-lung (right) ventilation (Figure 2).

Ports

A 1.5-cm camera port (for a 12-mm trocar) was created in the 8th intercostal space (ICS) at the left mid axillary line,
and three separate 1.0-cm working ports (for 8-mm trocars) were made in the 6th ICS (#1 arm) at the left anterior axillary line, the 8th ICS (#2 arm) at the left posterior axillary line, and the left 7th ICS (#3 arm), 2 cm from the spine. An auxiliary port (for a 12-mm trocar) was made in the 8th ICS near the costal arch (Figure 3).

**Installation of the surgical arms**

The robot patient cart was positioned directly above the operating table and then connected. The #2 arm was connected to a bipolar cautery forces, and the #1 arm was connected to a unipolar cautery hook. An incision protector was used in the auxiliary port.

**Surgical procedure**

See Figures 4-18.

**Postoperative condition**

Postoperative treatments included anti-inflammatory and phlegm-resolving treatments. The thoracic drainage tube was withdrawn 1 day after surgery, and the patient was discharged 3 days after surgery. No complications were observed during hospitalization. Pathological diagnosis was left upper lobe invasive adenocarcinoma. All lymph nodes were negative. Postoperative pathological stage was

**Discussion**

Originally, the robotic system was developed for cardiac surgery. The first internal mammary artery graft were performed in 1999 and 2000 (1,2). After these experiences, robotic systems were used in other fields, such as thoracic surgery for a wide range of procedures, starting with simple ones such as the resection of anterior or posterior mediastinal
masses (3-5). Robotic technology has certain advantages, especially in minimally invasive anatomic lung resection. The advantages of the robot compared with video-assisted thoracoscopic surgery include improved visualization, improved instrumentation that provides the surgeon with more degrees of movement, better lymph node visualization and dissection, high magnification, the ability to teach using a dual console, and a simulator (6). The left upper lobectomy is the most challenging of all lobectomies because of the complex arterial branches in the left upper lobe. In particular, the short branch A3 hemorrhages easily when dissociating and pulling. The da Vinci Surgical System has four mechanical arms. The #3 arm can help the surgeon find the pulling location, which reduces the assistant’s work. Hole of the #3 arm is relatively easy bleeding holes, beginners need to look at the punch. In all surgeries, we dissect the hilum using the posterior approach to expose the pulmonary artery which improves the safety. We inject CO2 before withdrawing the specimen of lung lobe to form a closed space, which can keep the operation field clear. The assistant uses a forceps tong with a gauze roll to pull the lobe to provide room for the surgeon. Straight nails are used to cut the vessels to lower the cost for the patients.
